

Jonathan joins a group of volunteer divers as part of an international event called the *Great Annual Fish Count* to take a census of marine life across the globe. His mission: dive the chilly waters of Massachusetts with a pencil...and count fish!

Objectives

- 1. Introduces viewers to a marine census and its function in biological monitoring.
- 2. Demonstrates techniques for taking a census of marine life using divers.

Questions for before watching the program

- 1. What is a census? What is another kind of census and why is it used?
- 2. Why might a census of fish be useful for biologists and policy-makers in government?
- 3. How might fish populations become "depleted" and how would a census (or series of censuses) reveal such a depletion?
- 4. Who might benefit from the information gained from a marine census and how?

Discussion for after watching the program

- 1. Why are divers ideally suited for taking a census of marine life?
- 2. How can a census help protect marine populations?
- 3. What basic tools does a diver use to take a marine census?
- 4. What are some of the fish that Jonathan saw during his marine census dive?
- 5. What makes a Torpedo Ray particularly effective as a hunter?
- 6. What characteristics make the flouder particularly well-suited for life on the bottom?
- 7. Why is it useful for all the counting in locations all over the world to be done at the same time?
